

DIP to SO-Plug Prototyping Adapters

Simplify prototyping and testing
Use actual size prototype boards
Great for microcontrollers and EE/Flash memory testing

Simple design is easy to use

These plugs and socket boards are simple and easy to use following this 3 step process.

1. Solder the SO-Plug to the prototype's SO land pattern.

Use your preferred soldering technique to attach the SO-Plug to the board's land pattern.

Hand soldering tip. Select either a very fine tip or a large tip with sharp angles. The sharp angles exploit the solder's surface tension to prevent solder bridges. Heat up the iron. Carefully align the plug on the land pattern. Solder the plug leads in opposite corners. Start at an unsoldered end pin. Using the capillary action of the tip, sweep down the row of pins. Wet each pin with solder then use the iron to pull the excess solder away from the pin.

2. Plug the DIP board onto the SO-Plug's header pins.

Note the pin one ends of the land pattern and the DIP Board. Align the SO-Plug's pins with the receptacles of the DIP Board. Press together until the pins bottom out in the receptacle. Some SO-Plugs will leave exposed pin between the receptacle and the SO-Plug's insulator.

3. Plug the emulator or erasable device into the DIP board.

The DIP Board provides either a production socket or ZIF socket for access to the prototype. Plug the device or development tool into the socket and start testing.

Product Selection

Use the cross reference to identify the correct SO-Plug for the SO device you are using. If your device is not in the cross reference, compare your prototype's land pattern to the recommended land patterns for each size plug. Select the Kit or component packs that fit your needs from the list below. The cross reference also provides the recommended DIP pattern for the device you are using. Confirm the DIP pin count and row spacing with your emulator or prototyping devices.
